Flask-Blogging is a Flask extension for adding Markdown based blog support to your site. It provides a flexible mechanism to store the data in the database of your choice. It is meant to work with the authentication provided by packages such as [Flask-Login](#) or [Flask-Security](#).

The philosophy behind this extension is to provide a lean app based on Markdown to provide blog support to your existing web application. This is contrary to some other packages such as [Flask-Blog](#) that are just blogs. If you already have a web app and you need to have a blog to communicate with your user or to promote your site through content based marketing, then Flask-Blogging would help you quickly get a blog up and running.

Out of the box, Flask-Blogging has support for the following:

- Bootstrap based site
- Markdown based blog editor
- Models to store blog
- Authentication of User's choice
- Sitemap, ATOM support
- Disqus support for comments
- Google analytics for usage tracking
- Permissions enabled to control which users can create/edit blogs
- Integrated Flask-Cache based caching for optimization
- Well documented, tested, and extensible design

- *Quick Start Example*
- *Configuring your Application*
  - *Adding Custom Markdown Extensions*
- *Configuration Variables*
- *Blog Views*
- *Permissions*
- *Screenshots*
  - *Blog Page*
  - *Blog Editor*
- *Useful Tips*
- *Release Notes*
- *Compatibility Notes*
- *API Documentation*
  - *Module contents*
  - *Submodules*
  - *flask\_blogging.engine module*
  - *flask\_blogging.processor module*
  - *flask\_blogging.sqlastorage module*
  - *flask\_blogging.storage module*
  - *flask\_blogging.views module*
  - *flask\_blogging.forms module*
  - *flask\_blogging.signals module*
- *Contributors*

---

## Quick Start Example

---

```
from flask import Flask, render_template_string, redirect
from sqlalchemy import create_engine, MetaData
from flask.ext.login import UserMixin, LoginManager, \
    login_user, logout_user
from flask.ext.blogging import SQLAlchemyStorage, BloggingEngine

app = Flask(__name__)
app.config["SECRET_KEY"] = "secret" # for WTF-forms and login
app.config["BLOGGING_URL_PREFIX"] = "/blog"
app.config["BLOGGING Disqus SITENAME"] = "test"
app.config["BLOGGING_SITEURL"] = "http://localhost:8000"

# extensions
engine = create_engine('sqlite:///tmp/blog.db')
meta = MetaData()
sql_storage = SQLAlchemyStorage(engine, metadata=meta)
blog_engine = BloggingEngine(app, sql_storage)
login_manager = LoginManager(app)
meta.create_all(bind=engine)

# user class for providing authentication
class User(UserMixin):
    def __init__(self, user_id):
        self.id = user_id

    def get_name(self):
        return "Paul Dirac" # typically the user's name

@login_manager.user_loader
@blog_engine.user_loader
def load_user(user_id):
    return User(user_id)

index_template = """
<!DOCTYPE html>
<html>
  <head> </head>
  <body>
    {% if current_user.is_authenticated %}
      <a href="/logout/">Logout</a>
    {% else %}
      <a href="/login/">Login</a>
    {% endif %}
  </body>
</html>

```

```
        &nbsp;&nbsp;<a href="/blog/">Blog</a>
        &nbsp;&nbsp;&nbsp;<a href="/blog/sitemap.xml">Sitemap</a>
        &nbsp;&nbsp;&nbsp;<a href="/blog/feeds/all.atom.xml">ATOM</a>
    </body>
</html>
"""

@app.route("/")
def index():
    return render_template_string(index_template)

@app.route("/login/")
def login():
    user = User("testuser")
    login_user(user)
    return redirect("/blog")

@app.route("/logout/")
def logout():
    logout_user()
    return redirect("/")

if __name__ == "__main__":
    app.run(debug=True, port=8000, use_reloader=True)
```

The key components required to get the blog hooked is explained below. Please note that as of Flask-Login 0.3.0 the `is_authenticated` attribute in the `UserMixin` is a property and not a method. Please use the appropriate option based on your Flask-Login version.

---

## Configuring your Application

---

The *BloggingEngine* class is the gateway to configure blogging support to your web app. You should create the *BloggingEngine* instance like this:

```
blogging_engine = BloggingEngine()
blogging_engine.init_app(app, storage)
```

You also need to pick the storage for blog. That can be done as:

```
from sqlalchemy import create_engine, MetaData

engine = create_engine("sqlite:///tmp/sqlite.db")
meta = MetaData()
storage = SQLAStorage(engine, metadata=meta)
meta.create_all(bind=engine)
```

Here we have created the storage, and created all the tables in the metadata. Once you have created the blogging engine, storage, and all the tables in the storage, you can connect with your app using the *init\_app* method as shown below:

```
blogging_engine.init_app(app, storage)
```

If you are using Flask-Sqlalchemy, you can do the following:

```
from flask.ext.sqlalchemy import SQLAlchemy

db = SQLAlchemy(app)
storage = SQLAStorage(db=db)
db.create_all()
```

One of the changes in version 0.3.1 is the ability for the user to provide the metadata object. This has the benefit of the table creation being passed to the user. Also, this gives the user the ability to use the common metadata object, and hence helps with the tables showing up in migrations while using Alembic.

As of version 0.5.2, support for the multi database scenario under Flask-SQLAlchemy was added. When we have a multiple database scenario, one can use the *bind* keyword in *SQLAStorage* to specify the database to bind to, as shown below:

```
# config value
SQLALCHEMY_BINDS = {
    'blog': "sqlite:///tmp/blog.db",
    'security': "sqlite:///tmp/security.db"
}
```

The storage can be initialised as:

```
db = SQLAlchemy(app)
storage = SQLAStorage(db=db, bind="blog")
db.create_all()
```

As of version 0.4.0, Flask-Cache integration is supported. In order to use caching in the blogging engine, you need to pass the Cache instance to the BloggingEngine as:

```
from flask.ext.cache import Cache
from flask.ext.blogging import BloggingEngine

blogging_engine = BloggingEngine(app, storage, cache)
```

*Flask-Blogging* lets the developer pick the authentication that is suitable, and hence requires her to provide a way to load user information. You will need to provide a *BloggingEngine.user\_loader* callback. This callback is used to load the user from the *user\_id* that is stored for each blog post. Just as in Flask-Login, it should take the *unicode user\_id* of a user, and return the corresponding user object. For example:

```
@blogging_engine.user_loader
def load_user(userid):
    return User.get(userid)
```

For the blog to have a readable display name, the User class must implement either the `get_name` method or the `__str__` method.

The BloggingEngine accepts an optional `extensions` argument. This is a list of Markdown extensions objects to be used during the markdown processing step.

As of version 0.6.0, a plugin interface is available to add new functionality. Custom processes can be added to the posts by subscribing to the `post_process_before` and `post_process_after` signals, and adding new functionality to it.

The BloggingEngine also accepts `post_processor` argument, which can be used to provide a custom post processor object to handle the processing of Markdown text. One way to do this would be to inherit the default `PostProcessor` object and override `process` method.

In version 0.4.1 and onwards, the BloggingEngine object can be accessed from your app as follows:

```
engine = app.extensions["blogging"]
```

The engine method also exposes a `get_posts` method to get the recent posts for display of posts in other views.

In earlier versions the same can be done using the key `FLASK_BLOGGING_ENGINE` instead of `blogging`. The use of `FLASK_BLOGGING_ENGINE` key will be deprecated moving forward.

## 2.1 Adding Custom Markdown Extensions

One can provide additional MarkDown extensions to the blogging engine. One example usage is adding the *codehilite* MarkDown extension. Additional extensions should be passed as a list while initializing the *BloggingEngine* as shown:

```
from markdown.extensions.codehilite import CodeHiliteExtension

extn1 = CodeHiliteExtension({})
blogging_engine = BloggingEngine(app, storage, extensions=[extn1])
```

This allows for the MarkDown to be processed using CodeHilite along with the default extensions. Please note that one would also need to include necessary static files in the *view*, such as for code highlighting to work.

---

## Configuration Variables

---

The Flask-Blogging extension can be configured by setting the following app config variables. These arguments are passed to all the views. The keys that are currently supported include:

- `BLOGGING_SITENAME` (*str*): The name of the blog to be used as the brand name. This is also used in the feed heading. (default “Flask-Blogging”)
- `BLOGGING_SITEURL` (*str*): The url of the site.
- `BLOGGING_RENDER_TEXT` (*bool*): Value to specify if the raw text should be rendered or not. (default `True`)
- `BLOGGING_DISQUS_SITENAME` (*str*): Disqus sitename for comments. A `None` value will disable comments. (default `None`)
- `BLOGGING_GOOGLE_ANALYTICS` (*str*): Google analytics code for usage tracking. A `None` value will disable google analytics. (default `None`)
- `BLOGGING_URL_PREFIX` (*str*) : The prefix for the URL of blog posts. A `None` value will have no prefix (default `None`).
- `BLOGGING_FEED_LIMIT` (*int*): The number of posts to limit to in the feed. If `None`, then all are shown, else will be limited to this number. (default `None`)
- `BLOGGING_PERMISSIONS` (*bool*): if `True`, this will enable permissions for the blogging engine. With permissions enabled, the user will need to have “blogger” `Role` to edit or create blog posts. Other authenticated users will not have blog editing permissions. The concepts here derive from `Flask-Principal` (default `False`)
- `BLOGGING_POSTS_PER_PAGE` (*int*): This sets the default number of pages to be displayed per page. (default 10)
- `BLOGGING_CACHE_TIMEOUT` (*int*): The timeout in seconds used to cache the blog pages. (default 60)

---

## Blog Views

---

There are various views that are exposed through Flask-Blogging. The URL for the various views are:

- `url_for('blogging.index')` (GET): The index blog posts with the first page of articles.
- `url_for('blogging.page_by_id', post_id=<post_id>)` (GET): The blog post corresponding to the `post_id` is retrieved.
- `url_for('blogging.posts_by_tag', tag=<tag_name>)` (GET): The list of blog posts corresponding to `tag_name` is returned.
- `url_for('blogging.posts_by_author', user_id=<user_id>)` (GET): The list of blog posts written by the author `user_id` is returned.
- `url_for('blogging.editor')` (GET, POST): The blog editor is shown. This view needs authentication and permissions (if enabled).
- `url_for('blogging.delete', post_id=<post_id>)` (POST): The blog post given by `post_id` is deleted. This view needs authentication and permissions (if enabled).
- `url_for('blogging.sitemap')` (GET): The sitemap with a link to all the posts is returned.
- `url_for('blogging.feed')` (GET): Returns ATOM feed URL.

The view can be easily customised by the user by overriding with their own templates. The template pages that need to be customized are:

- `blogging/index.html`: The blog index page used to serve index of posts, posts by tag, and posts by author
- `blogging/editor.html`: The blog editor page.
- `blogging/page.html`: The page that shows the given article.
- `blogging/sitemap.xml`: The sitemap for the blog posts.

---

## Permissions

---

In version 0.3.0 Flask-Blogging, enables permissions based on Flask-Principal. This addresses the issue of controlling which of the authenticated users can have access to edit or create blog posts. Permissions are enabled by setting `BLOGGING_PERMISSIONS` to `True`. Only users that have access to Role “blogger” will have permissions to create or edit blog posts.

## Dirac Equation

Posted by [Paul Dirac](#) on 03 Jun, 2015

In particle physics, the Dirac equation is a relativistic wave equation derived by British physicist Paul Dirac in 1928. In its free form, or including electromagnetic interactions, it describes all spin-1/2 massive particles, for which parity is a symmetry, such as electrons and quarks, and is consistent with both the principles of quantum mechanics and the theory of special relativity,[1] and was the first theory to account fully for special relativity in the context of quantum mechanics.

Dirac's Equation is given as:

$$(\beta mc^2 + c(\alpha_1 p_1 + \alpha_2 p_2 + \alpha_3 p_3)) \psi(x, t) = i\hbar \frac{\partial \psi(x, t)}{\partial t}$$

## Useful Tips

---

- **Migrations with Alembic:** (Applies to versions 0.3.0 and earlier) If you have migrations part of your project using Alembic, or extensions such as Flask-Migrate which uses Alembic, then you have to modify the Alembic configuration in order for it to ignore the Flask-Blogging related tables. If you don't set these modifications, then every time you run migrations, Alembic will not recognize the tables and mark them for deletion. And if you happen to upgrade by mistake then all your blog tables will be deleted. What we will do here is ask Alembic to exclude the tables used by Flask-Blogging. In your `alembic.ini` file, add a line:

```
[alembic:exclude]
tables = tag, post, tag_posts, user_posts
```

If you have a value set for `table_prefix` argument while creating the `SQLAlchemyStorage`, then the table names will contain that prefix in their names. In which case, you have to use appropriate names in the table names.

And in your `env.py`, we have to mark these tables as the ones to be ignored.

```
def exclude_tables_from_config(config_):
    tables_ = config_.get("tables", None)
    if tables_ is not None:
        tables = tables_.split(",")
    return tables

exclude_tables = exclude_tables_from_config(config.get_section('alembic:exclude'))

def include_object(object, name, type_, reflected, compare_to):
    if type_ == "table" and name in exclude_tables:
        return False
    else:
        return True

def run_migrations_online():
    """Run migrations in 'online' mode.

    In this scenario we need to create an Engine
    and associate a connection with the context.

    """
    engine = engine_from_config(
        config.get_section(config.config_ini_section),
        prefix='sqlalchemy.',
        poolclass=pool.NullPool)

    connection = engine.connect()
```

```
context.configure(  
    connection=connection,  
    target_metadata=target_metadata,  
    include_object=include_object,  
    compare_type=True  
)  
  
try:  
    with context.begin_transaction():  
        context.run_migrations()  
finally:  
    connection.close()
```

In the above, we are using `include_object` in `context.configure(...)` to be specified based on the `include_object` function.

---

## Release Notes

---

- **Version 0.6.0**

\*Released January 14, 2015

- The plugin framework for Flask-Blogging to allow users to add new features and capabilities.

- **Version 0.5.2**

*Released January 12, 2016*

- Added support for multiple binds for SQLAStorage

- **Version 0.5.1**

*Released December 6, 2015*

- Fixed the flexibility to add custom extensions to *BloggingEngine*.

- **Version 0.5.0**

*Released November 23, 2015*

- Fixed errors encountered while using Postgres database

- **Version 0.4.2**

*Released September 20, 2015*

- Added compatibility with Flask-Login version 0.3.0 and higher, especially to handle migration of `is_authenticated` attribute from method to property. (#43)

- **Version 0.4.1**

*Released September 16, 2015*

- Added javascript to center images in blog page
- Added method in blogging engine to render post and fetch post.

- **Version 0.4.0**

*Released July 26, 2015*

- Integrated Flask-Cache to optimize blog page rendering
- Fixed a bug where anonymous user was shown the new blog button

- **Version 0.3.2:**

*Released July 20, 2015*

- Fixed a bug in the edit post routines. The edited post would end up as a new one instead.

- **Version 0.3.1:**

*Released July 17, 2015*

- The `SQLAlchemyStorage` accepts metadata, and `SQLAlchemy` object as inputs. This adds the ability to keep the blogging table metadata synced up with other models. This feature adds compatibility with `Alchemic` autogenerate.
- Update docs to reflect the correct version number.

- **Version 0.3.0:**

*Released July 11, 2015*

- `Permissions` is a new feature introduced in this version. By setting `BLOGGING_PERMISSIONS` to `True`, one can restrict which of the users can create, edit or delete posts.
- Added `BLOGGING_POSTS_PER_PAGE` configuration variable to control the number of posts in a page.
- Documented the url construction procedure.

- **Version 0.2.1:**

*Released July 10, 2015*

- `BloggingEngine` `init_app` method can be called without having to pass a `storage` object.
- Hook tests to `setup.py` script.

- **Version 0.2.0:**

*Released July 6, 2015*

- `BloggingEngine` configuration moved to the `app` config setting. This breaks backward compatibility. See compatibility notes below.
- Added ability to limit number of posts shown in the feed through `app` configuration setting.
- The `setup.py` reads version from the module file. Improves version consistency.

- **Version 0.1.2:**

*Released July 4, 2015*

- Added Python 3.4 support

- **Version 0.1.1:**

*Released June 15, 2015*

- Fixed PEP8 errors
- Expanded `SQLAlchemyStorage` to include Postgres and MySQL flavors
- Added `post_date` and `last_modified_date` as arguments to the `Storage.save_post(...)` call for general compatibility

- **Version 0.1.0:**

*Released June 1, 2015*

- Initial Release
- Adds detailed documentation
- Supports Markdown based blog editor
- Has 90% code coverage in unit tests

---

## Compatibility Notes

---

- **Version 0.4.1:**

The documented way to get the blogging engine from app is using the key `blogging` from `app.extensions`.

- **Version 0.3.1:**

The `SQLAStorage` will accept metadata and set it internally. The database tables will not be created automatically. The user would need to invoke `create_all` in the metadata or `SQLAlchemy` object in `Flask-SQLAlchemy`.

- **Version 0.3.0:**

- In this release, the templates folder was renamed from `blog` to `blogging`. To override the existing templates, you will need to create your templates in the `blogging` folder.
- The blueprint name was renamed from `blog_api` to `blogging`.

- **Version 0.2.0:**

In this version, `BloggingEngine` will no longer take `config` argument. Instead, all configuration can be done through app config variables. Another `BloggingEngine` parameter, `url_prefix` is also available only through config variable.

---

## API Documentation

---

### 10.1 Module contents

### 10.2 Submodules

### 10.3 flask\_blogging.engine module

The BloggingEngine module.

```
class flask_blogging.engine.BloggingEngine (app=None,                                storage=None,
                                           post_processor=None,          extensions=None,
                                           cache=None)
```

Bases: object

The BloggingEngine is the class for initializing the blog support for your web app. Here is an example usage:

```
from flask import Flask
from flask.ext.blogging import BloggingEngine, SQLAlchemyStorage
from sqlalchemy import create_engine

app = Flask(__name__)
db_engine = create_engine("sqlite:///tmp/sqlite.db")
meta = MetaData()
storage = SQLAlchemyStorage(db_engine, metadata=meta)
blog_engine = BloggingEngine(app, storage)
```

```
__init__ (app=None, storage=None, post_processor=None, extensions=None, cache=None)
```

#### Parameters

- **app** (*object*) – Optional app to use
- **storage** (*object*) – The blog storage instance that implements the `Storage` class interface.
- **post\_processor** (*object*) – (optional) The post processor object. If none provided, the default post processor is used.
- **extensions** (*list*) – (optional) A list of markdown extensions to add to post processing step.
- **cache** (*Object*) – (Optional) A Flask-Cache object to enable caching

#### Returns

**blogger\_permission**

**get\_posts** (*count=10, offset=0, recent=True, tag=None, user\_id=None, include\_draft=False, render=False*)

**classmethod get\_user\_name** (*user*)

**init\_app** (*app, storage=None, cache=None*)  
Initialize the engine.

#### Parameters

- **app** (*Object*) – The app to use
- **storage** (*Object*) – The blog storage instance that implements the
- **cache** (*Object Storage class interface.*) – (Optional) A Flask-Cache object to enable caching

**is\_user\_blogger** ()

**process\_post** (*post, render=True*)

A high level view to create post processing. :param post: Dictionary representing the post :type post: dict  
:param render: Choice if the markdown text has to be converted or not :type render: bool :return:

**user\_loader** (*callback*)

The decorator for loading the user.

**Parameters** **callback** – The callback function that can load a user given a unicode `user_id`.

**Returns** The callback function

## 10.4 flask\_blogging.processor module

**class** flask\_blogging.processor.**PostProcessor**

Bases: object

**classmethod all\_extensions** ()

**classmethod construct\_url** (*post*)

**static create\_slug** (*title*)

**classmethod is\_author** (*post, user*)

**classmethod process** (*post, render=True*)

This method takes the post data and renders it :param post: :param render: :return:

**classmethod render\_text** (*post*)

**classmethod set\_custom\_extensions** (*extensions*)

## 10.5 flask\_blogging.sqlastorage module

**class** flask\_blogging.sqlastorage.**SQLAStorage** (*engine=None, table\_prefix='', meta-data=None, db=None, bind=None*)

Bases: flask\_blogging.storage.Storage

The SQLAStorage implements the interface specified by the Storage class. This class uses SQLAlchemy to implement storage and retrieval of data from any of the databases supported by SQLAlchemy.

`__init__` (*engine=None, table\_prefix='', metadata=None, db=None, bind=None*)

The constructor for the `SQLAStorage` class.

**Parameters** **engine** – The `SQLAlchemy` engine instance created by calling

`create_engine`. One can also use `Flask-SQLAlchemy`, and pass the engine property. :type engine: object :param table\_prefix: (Optional) Prefix to use for the tables created

(default "").

**Parameters**

- **metadata** (*object*) – (Optional) The `SQLAlchemy` `MetaData` object
- **db** (*object*) – (Optional) The `Flask-SQLAlchemy` `SQLAlchemy` object
- **bind** – (Optional) Reference the database to bind for multiple

database scenario with binds :type bind: str

`count_posts` (*tag=None, user\_id=None, include\_draft=False*)

Returns the total number of posts for the give filter

**Parameters**

- **tag** (*str*) – Filter by a specific tag
- **user\_id** (*str*) – Filter by a specific user
- **include\_draft** (*bool*) – Whether to include posts marked as draft or not

**Returns** The number of posts for the given filter.

`delete_post` (*post\_id*)

Delete the post defined by `post_id`

**Parameters** **post\_id** (*int*) – The identifier corresponding to a post

**Returns** Returns True if the post was successfully deleted and False otherwise.

`get_post_by_id` (*post\_id*)

Fetch the blog post given by `post_id`

**Parameters** **post\_id** (*int*) – The post identifier for the blog post

**Returns** If the `post_id` is valid, the post data is retrieved, else returns `None`.

`get_posts` (*count=10, offset=0, recent=True, tag=None, user\_id=None, include\_draft=False*)

Get posts given by filter criteria

**Parameters**

- **count** (*int*) – The number of posts to retrieve (default 10)
- **offset** (*int*) – The number of posts to offset (default 0)
- **recent** (*bool*) – Order by recent posts or not
- **tag** (*str*) – Filter by a specific tag
- **user\_id** (*str*) – Filter by a specific user
- **include\_draft** (*bool*) – Whether to include posts marked as draft or not

**Returns** A list of posts, with each element a dict containing values for the following keys: (title, text, draft, post\_date, last\_modified\_date). If count is `None`, then all the posts are returned.

**metadata**

## post\_table

**save\_post** (*title, text, user\_id, tags, draft=False, post\_date=None, last\_modified\_date=None, meta\_data=None, post\_id=None*)

Persist the blog post data. If `post_id` is `None` or `post_id` is invalid, the post must be inserted into the storage. If `post_id` is a valid id, then the data must be updated.

### Parameters

- **title** (*str*) – The title of the blog post
- **text** (*str*) – The text of the blog post
- **user\_id** (*str*) – The user identifier
- **tags** (*list*) – A list of tags
- **draft** (*bool*) – (Optional) If the post is a draft of if needs to be published. (default `False`)
- **post\_date** (*datetime.datetime*) – (Optional) The date the blog was posted (default `datetime.datetime.utcnow()` )
- **last\_modified\_date** (*datetime.datetime*) – (Optional) The date when blog was last modified (default `datetime.datetime.utcnow()` )
- **post\_id** (*int*) – (Optional) The post identifier. This should be `None` for an insert call, and a valid value for update. (default `None`)

**Returns** The `post_id` value, in case of a successful insert or update. Return `None` if there were errors.

## tag\_posts\_table

## tag\_table

## user\_posts\_table

# 10.6 flask\_blogging.storage module

**class** `flask_blogging.storage.Storage`

Bases: `object`

**count\_posts** (*tag=None, user\_id=None, include\_draft=False*)

Returns the total number of posts for the give filter

### Parameters

- **tag** (*str*) – Filter by a specific tag
- **user\_id** (*str*) – Filter by a specific user
- **include\_draft** (*bool*) – Whether to include posts marked as draft or not

**Returns** The number of posts for the given filter.

**delete\_post** (*post\_id*)

Delete the post defined by `post_id`

**Parameters** **post\_id** (*int*) – The identifier corresponding to a post

**Returns** Returns `True` if the post was successfully deleted and `False` otherwise.

**get\_post\_by\_id** (*post\_id*)

Fetch the blog post given by `post_id`

**Parameters** `post_id` (*int*) – The post identifier for the blog post

**Returns** If the `post_id` is valid, the post data is retrieved,  
else returns `None`.

**get\_posts** (*count=10, offset=0, recent=True, tag=None, user\_id=None, include\_draft=False*)

Get posts given by filter criteria

**Parameters**

- **count** (*int*) – The number of posts to retrieve (default 10). If count is `None`, all posts are returned.
- **offset** (*int*) – The number of posts to offset (default 0)
- **recent** (*bool*) – Order by recent posts or not
- **tag** (*str*) – Filter by a specific tag
- **user\_id** (*str*) – Filter by a specific user
- **include\_draft** (*bool*) – Whether to include posts marked as draft or not

**Returns** A list of posts, with each element a dict containing values for the following keys: (title, text, draft, post\_date, last\_modified\_date). If count is `None`, then all the posts are returned.

**static normalize\_tags** (*tags*)

**save\_post** (*title, text, user\_id, tags, draft=False, post\_date=None, last\_modified\_date=None, meta\_data=None, post\_id=None*)

Persist the blog post data. If `post_id` is `None` or `post_id` is invalid, the post must be inserted into the storage. If `post_id` is a valid id, then the data must be updated.

**Parameters**

- **title** (*str*) – The title of the blog post
- **text** (*str*) – The text of the blog post
- **user\_id** (*str*) – The user identifier
- **tags** (*list*) – A list of tags
- **draft** (*bool*) – If the post is a draft or if needs to be published.
- **post\_date** (*datetime.datetime*) – (Optional) The date the blog was posted (default `datetime.datetime.utcnow()`)
- **last\_modified\_date** (*datetime.datetime*) – (Optional) The date when blog was last modified (default `datetime.datetime.utcnow()`)
- **meta\_data** (*dict*) – The meta data for the blog post
- **post\_id** (*int*) – The post identifier. This should be `None` for an insert call, and a valid value for update.

**Returns** The `post_id` value, in case of a successful insert or update.

Return `None` if there were errors.

## 10.7 flask\_blogging.views module

`flask_blogging.views.cached_func` (*blogging\_engine, func*)

`flask_blogging.views.create_blueprint` (*import\_name, blogging\_engine*)

`flask_blogging.views.delete` (*\*args, \*\*kwargs*)

`flask_blogging.views.editor` (*\*args, \*\*kwargs*)

`flask_blogging.views.feed` ()

`flask_blogging.views.index` (*count, page*)

Serves the page with a list of blog posts

### Parameters

- **count** –
- **offset** –

### Returns

`flask_blogging.views.page_by_id` (*post\_id, slug*)

`flask_blogging.views.posts_by_author` (*user\_id, count, page*)

`flask_blogging.views.posts_by_tag` (*tag, count, page*)

`flask_blogging.views.sitemap` ()

`flask_blogging.views.unless` (*blogging\_engine*)

## 10.8 flask\_blogging.forms module

```
class flask_blogging.forms.BlogEditor (formdata=<class flask_wtf.form._Auto>,  obj=None,
                                       prefix='',  csrf_context=None,  secret_key=None,
                                       csrf_enabled=None, *args, **kwargs)
```

```
    draft = <UnboundField(BooleanField, ('draft'), {'default': False})>
```

```
    submit = <UnboundField(SubmitField, ('submit'), {})>
```

```
    tags = <UnboundField(StringField, ('tags'), {'validators': [<wtforms.validators.DataRequired object at 0x7f6019f09b50]>}]>
```

```
    text = <UnboundField(TextAreaField, ('text'), {'validators': [<wtforms.validators.DataRequired object at 0x7f6019f09a50]>}]>
```

```
    title = <UnboundField(StringField, ('title'), {'validators': [<wtforms.validators.DataRequired object at 0x7f6019f09a50]>}]>
```

## 10.9 flask\_blogging.signals module

The flask\_blogging signals module

```
flask_blogging.signals = <module 'flask_blogging.signals' from '/home/docs/checkouts/readthedocs.org/user_builds/flask_blogging/checkouts/0.6.0/flask_blogging/signals.py'>
```

The flask\_blogging signals module

```
flask_blogging.signals.engine_initialised = <blinker.base.NamedSignal object at 0x7f601ad6b790; 'engine_init'>
```

Signal send by the BloggingEngine after the object is initialized. The arguments passed by the signal are:

### Parameters

- **app** (*object*) – The Flask app which is the sender
- **engine** (*object*) – The blogging engine that was initialized

`flask_blogging.signals.post_processed = <blinker.base.NamedSignal object at 0x7f601ad6b7d0; 'post_processed'>`

Signal sent when a post is processed (i.e., the markdown is converted to html text). The arguments passed along with this signal are:

#### Parameters

- **app** (*object*) – The Flask app which is the sender
- **engine** (*object*) – The blogging engine that was initialized
- **post** (*dict*) – The post object which was processed
- **render** (*bool*) – Flag to denote if the post is to be rendered or not

`flask_blogging.signals.page_by_id_fetched = <blinker.base.NamedSignal object at 0x7f601ad6b810; 'page_by_id'>`

Signal sent when a blog page specified by `id` is fetched, and prior to the post being processed.

#### Parameters

- **app** (*object*) – The Flask app which is the sender
- **engine** (*object*) – The blogging engine that was initialized
- **post** (*dict*) – The post object which was fetched
- **meta** (*dict*) – The metadata associated with that page
- **post\_id** (*int*) – The identifier of the post
- **slug** (*str*) – The slug associated with the page

`flask_blogging.signals.page_by_id_processed = <blinker.base.NamedSignal object at 0x7f601ad6b850; 'page_by_id'>`

Signal sent when a blog page specified by `id` is fetched, and prior to the post being processed.

#### Parameters

- **app** (*object*) – The Flask app which is the sender
- **engine** (*object*) – The blogging engine that was initialized
- **post** (*dict*) – The post object which was processed
- **meta** (*dict*) – The metadata associated with that page
- **post\_id** (*int*) – The identifier of the post
- **slug** (*str*) – The slug associated with the page

`flask_blogging.signals.posts_by_tag_fetched = <blinker.base.NamedSignal object at 0x7f601ad6b890; 'posts_by_tag'>`

Signal sent when posts are fetched for a given tag but before processing

#### Parameters

- **app** (*object*) – The Flask app which is the sender
- **engine** (*object*) – The blogging engine that was initialized
- **posts** (*list*) – Lists of post fetched with a given tag
- **meta** (*dict*) – The metadata associated with that page
- **tag** (*str*) – The tag that is requested
- **count** (*int*) – The number of posts per page
- **page** (*int*) – The page offset

`flask_blogging.signals.posts_by_tag_processed = <blinker.base.NamedSignal object at 0x7f601ad6b8d0; 'posts_`  
Signal sent after posts for a given tag were fetched and processed

**Parameters**

- **app** (*object*) – The Flask app which is the sender
- **engine** (*object*) – The blogging engine that was initialized
- **posts** (*list*) – Lists of post fetched and processed with a given tag
- **meta** (*dict*) – The metadata associated with that page
- **tag** (*str*) – The tag that is requested
- **count** (*int*) – The number of posts per page
- **page** (*int*) – The page offset

`flask_blogging.signals.posts_by_author_fetched = <blinker.base.NamedSignal object at 0x7f601ad6b910; 'post`  
Signal sent after posts by an author were fetched but before processing

**Parameters**

- **app** (*object*) – The Flask app which is the sender
- **engine** (*object*) – The blogging engine that was initialized
- **posts** (*list*) – Lists of post fetched with a given author
- **meta** (*dict*) – The metadata associated with that page
- **user\_id** (*str*) – The `user_id` for the author
- **count** (*int*) – The number of posts per page
- **page** (*int*) – The page offset

`flask_blogging.signals.posts_by_author_processed = <blinker.base.NamedSignal object at 0x7f601ad6b950; 'p`  
Signal sent after posts by an author were fetched and processed

**Parameters**

- **app** (*object*) – The Flask app which is the sender
- **engine** (*object*) – The blogging engine that was initialized
- **posts** (*list*) – Lists of post fetched and processed with a given author
- **meta** (*dict*) – The metadata associated with that page
- **user\_id** (*str*) – The `user_id` for the author
- **count** (*int*) – The number of posts per page
- **page** (*int*) – The page offset

`flask_blogging.signals.index_posts_fetched = <blinker.base.NamedSignal object at 0x7f601ad6b990; 'index_pos`  
Signal sent after the posts for the index page are fetched

**Parameters**

- **app** (*object*) – The Flask app which is the sender
- **engine** (*object*) – The blogging engine that was initialized
- **posts** (*list*) – Lists of post fetched for the index page
- **meta** (*dict*) – The metadata associated with that page

- **count** (*int*) – The number of posts per page
- **page** (*int*) – The page offset

`flask_blogging.signals.index_posts_processed = <blinker.base.NamedSignal object at 0x7f601ad6b9d0; 'index_posts_processed'>`  
Signal sent after the posts for the index page are fetched and processed

#### Parameters

- **app** (*object*) – The Flask app which is the sender
- **engine** (*object*) – The blogging engine that was initialized
- **posts** (*list*) – Lists of post fetched and processed with a given author
- **meta** (*dict*) – The metadata associated with that page
- **count** (*int*) – The number of posts per page
- **page** (*int*) – The page offset

`flask_blogging.signals.feed_posts_fetched = <blinker.base.NamedSignal object at 0x7f601ad6ba10; 'feed_posts_fetched'>`  
Signal send after feed posts are fetched

#### Parameters

- **app** (*object*) – The Flask app which is the sender
- **engine** (*object*) – The blogging engine that was initialized
- **posts** (*list*) – Lists of post fetched and processed with a given author

`flask_blogging.signals.feed_posts_processed = <blinker.base.NamedSignal object at 0x7f601ad6ba50; 'feed_posts_processed'>`  
Signal send after feed posts are processed

#### Parameters

- **app** (*object*) – The Flask app which is the sender
- **engine** (*object*) – The blogging engine that was initialized
- **feed** (*list*) – Feed of post fetched and processed

`flask_blogging.signals.sitemap_posts_fetched = <blinker.base.NamedSignal object at 0x7f601ad6ba90; 'sitemap_posts_fetched'>`  
Signal send after posts are fetched

#### Parameters

- **app** (*object*) – The Flask app which is the sender
- **engine** (*object*) – The blogging engine that was initialized
- **posts** (*list*) – Lists of post fetched and processed with a given author

`flask_blogging.signals.sitemap_posts_processed = <blinker.base.NamedSignal object at 0x7f601ad6bad0; 'sitemap_posts_processed'>`  
Signal send after posts are fetched and processed

#### Parameters

- **app** (*object*) – The Flask app which is the sender
- **engine** (*object*) – The blogging engine that was initialized
- **posts** (*list*) – Lists of post fetched and processed with a given author

`flask_blogging.signals.editor_post_saved = <blinker.base.NamedSignal object at 0x7f601ad6bb10; 'editor_post_saved'>`  
Signal sent after a post was saved during the POST request

#### Parameters

- **app** (*object*) – The Flask app which is the sender
- **engine** (*object*) – The blogging engine that was initialized
- **post\_id** (*int*) – The id of the post that was deleted
- **user** (*object*) – The user object
- **post** (*object*) – The post that was deleted

`flask_blogging.signals.editor_get_fetched = <blinker.base.NamedSignal object at 0x7f601ad6bb50; 'editor_get_fetched'>`  
Signal sent after fetching the post during the GET request

#### Parameters

- **app** (*object*) – The Flask app which is the sender
- **engine** (*object*) – The blogging engine that was initialized
- **post\_id** (*int*) – The id of the post that was deleted
- **form** (*object*) – The form prepared for the editor display

`flask_blogging.signals.post_deleted = <blinker.base.NamedSignal object at 0x7f601ad6bb90; 'post_deleted'>`  
The signal sent after the post is deleted.

#### Parameters

- **app** (*object*) – The Flask app which is the sender
- **engine** (*object*) – The blogging engine that was initialized
- **post\_id** (*int*) – The id of the post that was deleted
- **post** (*object*) – The post that was deleted

`flask_blogging.signals.blueprint_created = <blinker.base.NamedSignal object at 0x7f601ad6bbd0; 'blueprint_created'>`  
The signal sent after the blueprint is created. A good time to add other views to the blueprint.

#### Parameters

- **app** (*object*) – The Flask app which is the sender
- **engine** (*object*) – The blogging engine that was initialized
- **blueprint** (*object*) – The blog app blueprint

`flask_blogging.signals.sqla_initialized = <blinker.base.NamedSignal object at 0x7f601ad6bc10; 'sqla_initialized'>`  
Signal sent after the SQLAlchemyStorage object is initialized

#### Parameters

- **sqlastorage** (*object*) – The SQLAlchemyStorage object
- **engine** (*object*) – The blogging engine that was initialized
- **table\_prefix** (*str*) – The prefix to use for tables
- **meta** (*object*) – The metadata for the database
- **bind** (*object*) – The bind value in the multiple db scenario.
